

Tilted-logistic family: band symmetric about logistic. Top row: probes at fixed DISTANCE past the edge. Bottom row: swept over all out-of-band POSITIONS.

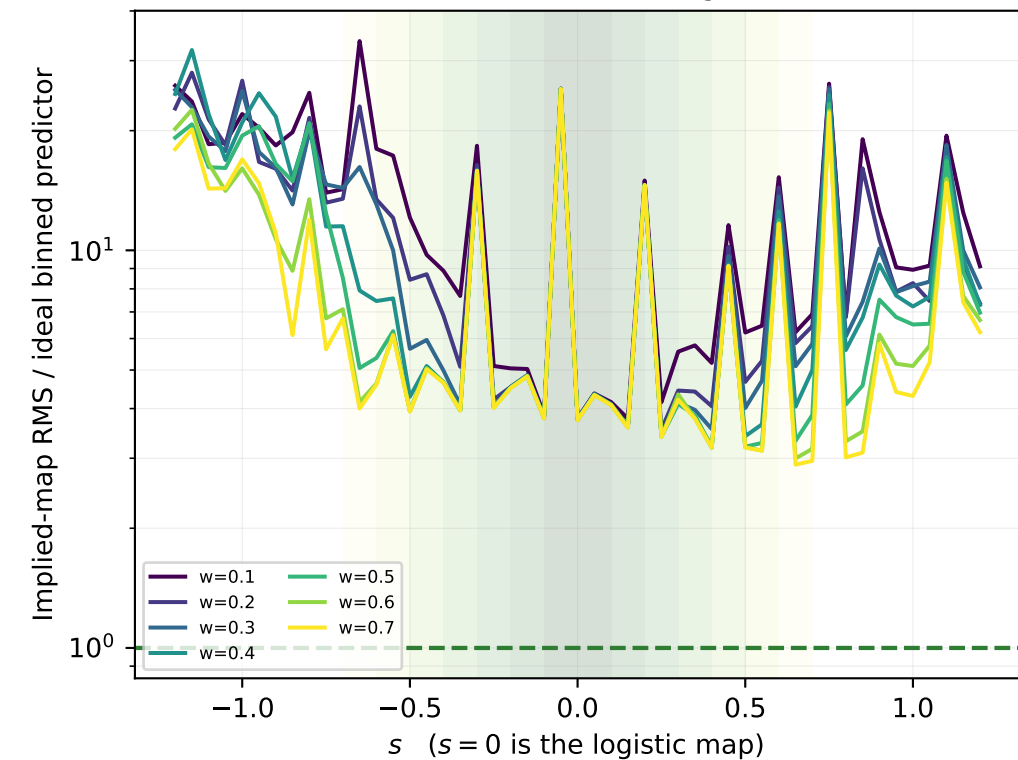

Does identification reach the floor off-band?
clamping to the band edge cannot

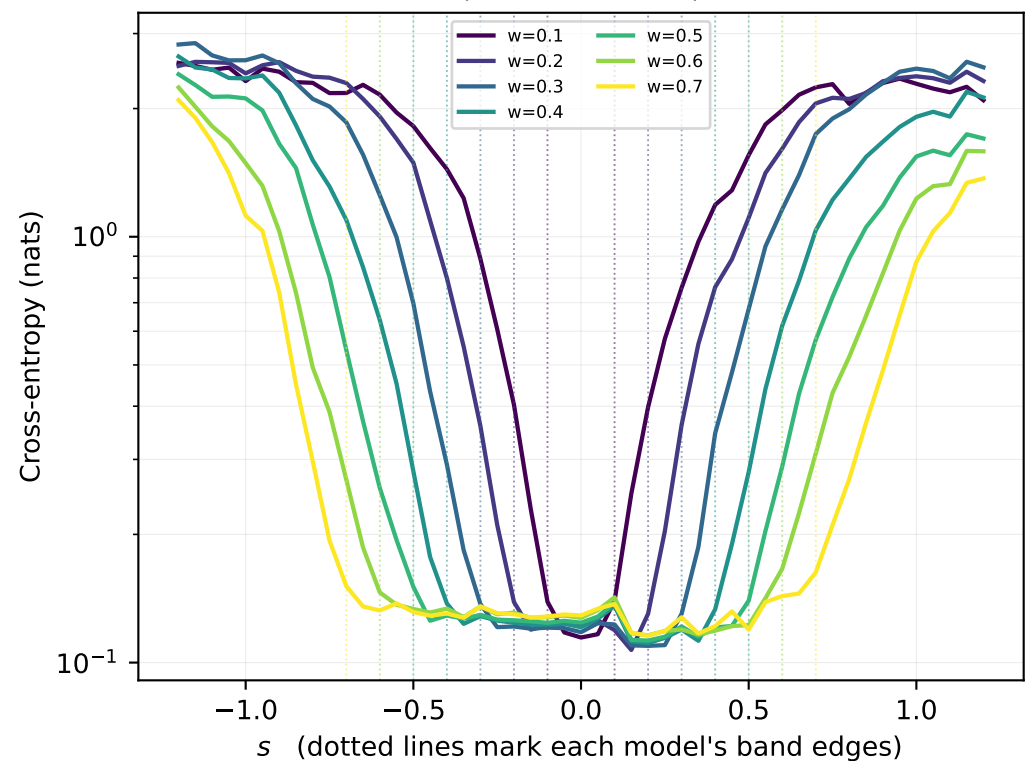

Loss at a fixed distance past the band edge

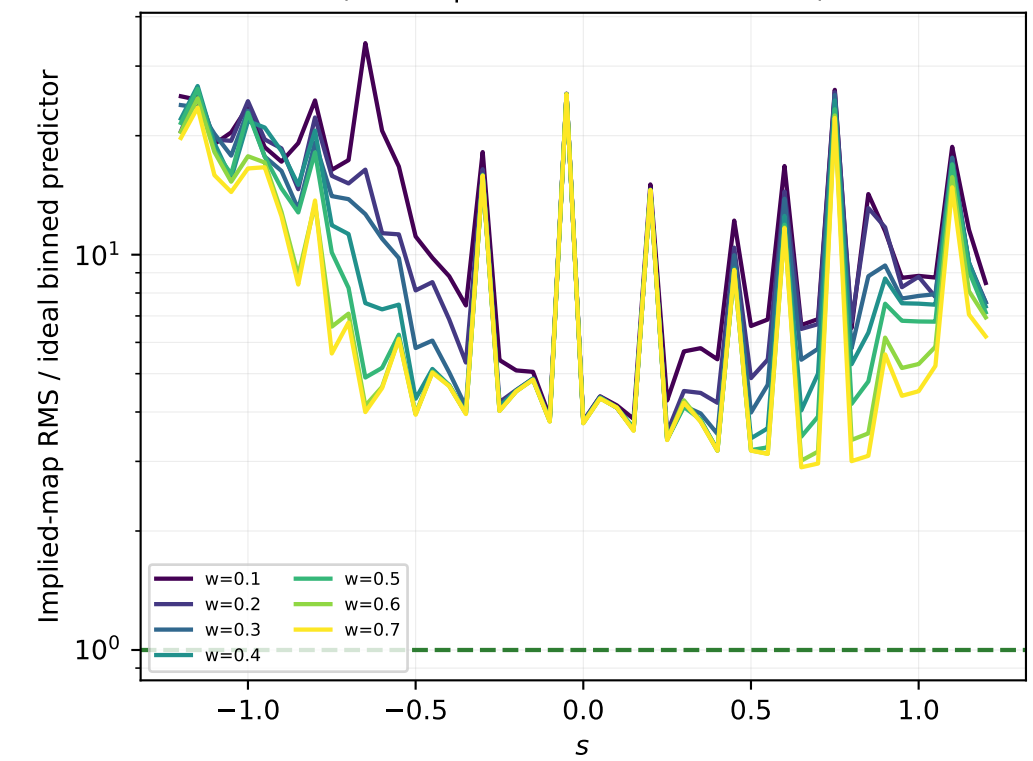

Identification quality across the whole family
(seed 0; flat at 1.0 would be full generalization)

Position-swept: loss at every s
(the classic view)

Position-swept: identification quality at every s
(1.0 = optimal for a binned model)

Fixed position vs fixed distance
curves ending early = that s fell inside the band
